(Received: December 15, 1997)

**SUMMARY:** By using the semiclassical-perturbation formalism, we have calculated electron-, proton-, and He III-impact line widths and shifts for 14 O VII multiplets and 18 Mg XI multiplets, of importance for research, diagnostic and modeling of various astrophysical, laser produced, fusion and laboratory plasmas. For O VII calculations were performed for temperature range from 100,000 K to 2,000,000 K. and perturber densities ( $10^{17} \text{ cm}^{-3}$  -  $10^{23} \text{ cm}^{-3}$ ). For Mg XI calculations were performed for temperature range from 500,000 K to 5,000,000 K. and perturber densities  $10^{18} \text{ cm}^{-3}$  -  $10^{24} \text{ cm}^{-3}$ .

## 1. INTRODUCTION

Due to the high cosmical abundance of magnesium and particularly oxygen, Stark broadening parameters of spectral lines for their various ionization stages are of interest for a number of astrophysical problems (see, e.g., Dimitrijević and Sahal-Bréchot 1998a).

As a continuation of our project (Dimitrijević 1996) to provide an as large as possible set of reliable Stark broadening data needed for the consideration and modeling of astrophysical and laboratory plasmas as well as for investigations of laser produced and fusion plasmas and plasmas in technology, we have calculated within the semiclassical-perturbation formalism (Sahal-Bréchot 1969ab, see also Sahal-Bréchot 1974, Fleurier *et al.* 1977, Dimitrijević and Sahal-Bréchot 1984, Dimitrijević *et al.* 1991, Dimitrijević and Sahal-Bréchot 1995) electron-, proton-,

and He III-impact line widths and shifts for 14 O VII and 18 Mg XI multiplets. The theoretical formalism will not be discussed here, since it has been reviewed several times, as, e.g., briefly in Dimitrijević and Sahal-Bréchot, 1995.

## 2. RESULTS AND DISCUSSION

All details of the calculation procedure as well as the result analysis, will be published in Dimitrijević and Sahal-Bréchot 1998b. Here, only tables of Stark broadening parameters will be shown. Atomic energy levels needed for calculations have been taken from Isler *et al.* (1993) for O VII, and from Martin and Zalubas (1980) for Mg XI. Our results for 14 O VII multiplets are shown in Table 1, for perturber densities  $10^{17}$  –  $10^{23} \text{ cm}^{-3}$ , and temperatures  $T = 100,000$  –  $2,000,000$  K. The obtained results for 18

**Table 1.** This table shows electron-, proton-, and He III-impact broadening parameters for O VII for perturber densities of  $10^{17} - 10^{23}$  cm $^{-3}$  and temperatures from 100,000 up to 2,000,000 K. Stark broadening parameters for densities lower than tabulated, are linear with perturber density. Transitions and averaged wavelengths for the multiplet (in Å) are also given in the table. By dividing c by the corresponding full width at half maximum (Dimitrijević *et al.*, 1991), we obtain an estimate for the maximum perturber density for which the line may be treated as isolated and tabulated data may be used. The asterisk identifies cases for which the collision volume multiplied by the perturber density (the condition for validity of the impact approximation) lies between 0.1 and 0.5.

**Table 2.** This table shows electron-, proton-, and He III-impact broadening parameters for Mg XI for perturber densities of  $10^{18}$ – $10^{24}$  cm $^{-3}$  and temperatures from 500,000 up to 5,000,000 K. Stark broadening parameters for densities lower than tabulated, are linear with perturber density. Transitions and averaged wavelengths for the multiplet (in Å) are also given in the table. By dividing c by the corresponding full width at half maximum (Dimitrijević *et al.*, 1991), we obtain an estimate for the maximum perturber density for which the line may be treated as isolated and tabulated data may be used. The asterisk identifies cases for which the collision volume multiplied by the perturber density (the condition for validity of the impact approximation) lies between 0.1 and 0.5.

PERTURBER DENSITY = 1.E+18cm $^{-3}$

Mg XI multiplets are shown in Table 2, for perturber densities  $10^{18} - 10^{24} \text{ cm}^{-3}$ , and temperatures  $T = 500,000 - 5,000,000 \text{ K}$ . The complete set of data is given for the perturber density of  $10^{19} \text{ cm}^{-3}$  in both cases. For lower perturber densities, only data needed for better interpolation are given. Stark broadening parameters for densities lower than tabulated, or for transitions not tabulated for perturber densities lower than  $10^{19} \text{ cm}^{-3}$ , are linear with perturber density. The parameter  $c$  (Dimitrijević and Sahal–Bréchot 1984) gives an estimate for the maximum perturber density for which the line may be treated as isolated when divided by the corresponding full width at half maximum. For each value given in Tables 1 and 2, the collision volume ( $V$ ) multiplied by the perturber density ( $N$ ) is much less than one, and the impact approximation is valid (Sahal–Bréchot 1969ab). Values for  $NV > 0.5$  are not given and values for  $0.1 < NV \leq 0.5$  are denoted by an asterisk. When the impact approximation is not valid, the ion broadening contribution may be estimated by using quasistatic approach (Sahal–Bréchot 1991 or Griem 1974). In the region between where neither of these two approximations is valid, a unified type theory should be used. For example in Barnard et al. (1974) a simple analytical formula for such a case is given. The accuracy of the results obtained decreases when broadening by ion interactions becomes important.

We hope that the present results might be useful for a number of problems in stellar and laboratory plasma research, modeling and diagnostic.
